

# Coated nanoparticles in solvents and at interfaces

**J. Matthew Lane**

Sandia National Laboratories

Albuquerque, NM

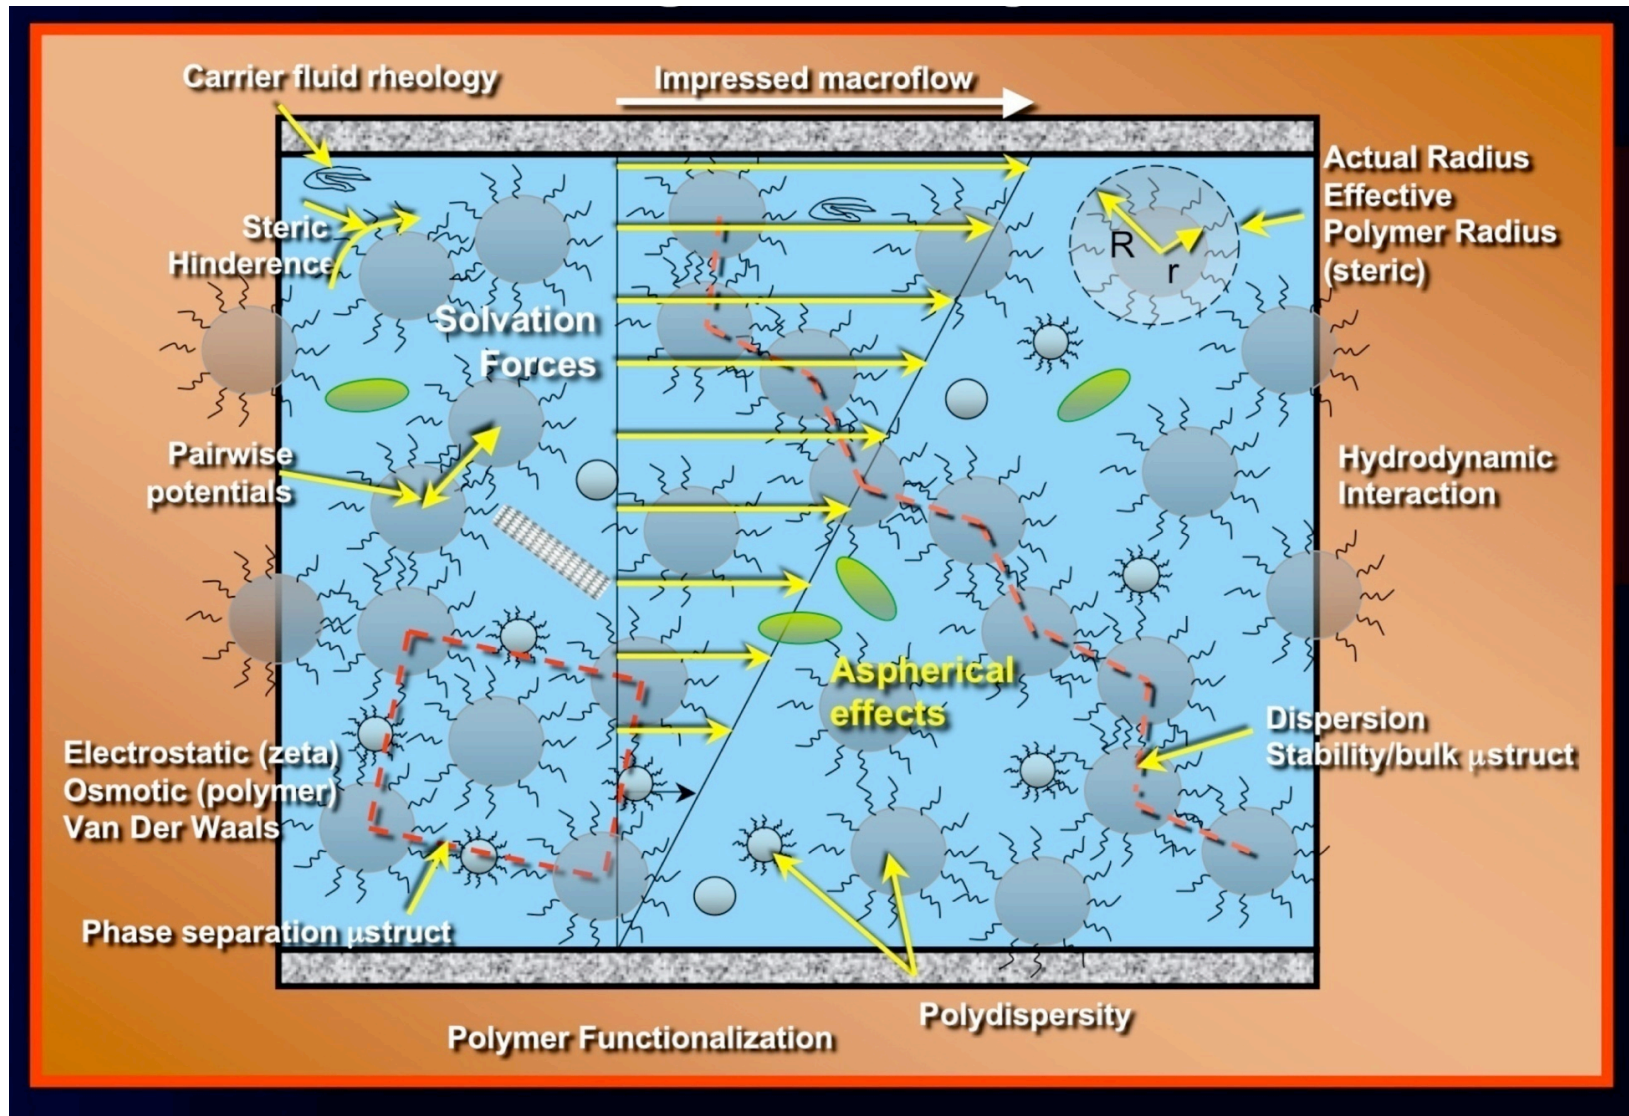

**25 February 2010**

**LAMMPS Workshop**

Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

# Problem description

Courtesy of P. R. Schunk

## System details

---

- Polyethylene oxide PEO(6) coated 5nm silica nanoparticle in water (3 chains/nm<sup>2</sup>)

Amorphous silica particles

- 5 nm diameter
- Treated as rigid objects

PEO chains

- ca. 240 per 5 nm particle
- Attached at OH sites

Water solvent used with PEO

MD run details

- $T = 300$  K
- 10 Å cutoff on pair potentials
- $4 \times 10^5 - 7.2 \times 10^6$  atoms
- Timestep 1fs – runs of 5-10ns

Lane et al, PRE 79, 050501 (2009)

## Interactions between nanoparticles

---

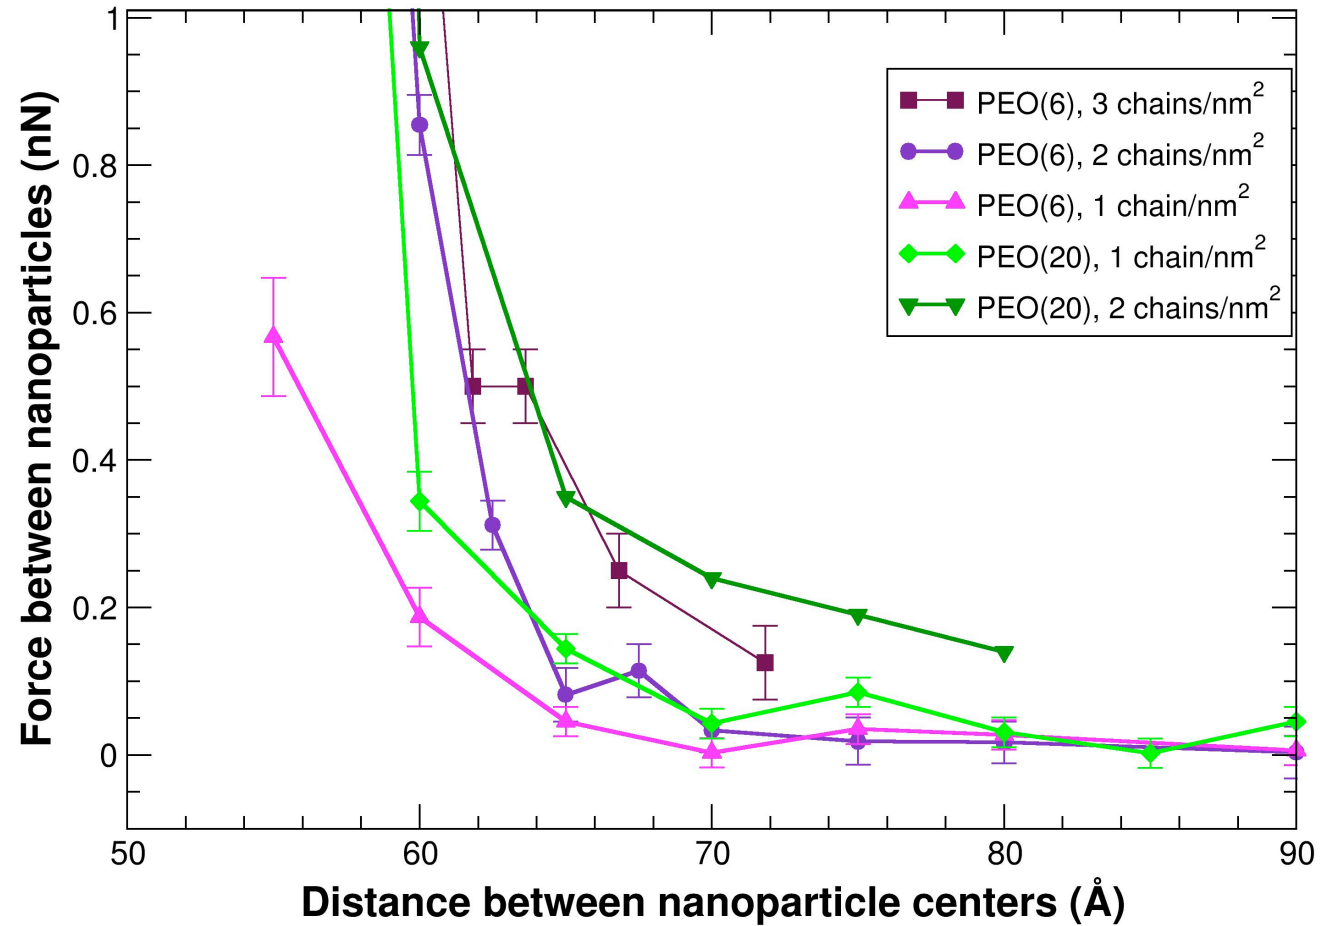

- Determine velocity independent (solvation) and velocity dependent (lubrication) forces
  - chain length, nanoparticle size/shape, coverage
- Integrate into coarse-grained model

# Interactions between nanoparticles

## PEO-coated silica NP in water

---

- PEO(20), 1.0 chains/nm<sup>2</sup>

- PEO(100), 0.5 chains/nm<sup>2</sup>

- Mitra et al, Langmuir 19, 8994 (2003) – exp. - PEO(100), 0.2chains/nm<sup>2</sup>

# Constructing model Au-thiol nanoparticles

---

## Fact sheet:

2, 4, and 8 nm diameter core with Au implicit

S-(CH<sub>2</sub>)<sub>9</sub>-X and S-(CH<sub>2</sub>)<sub>17</sub>-X where X = CH<sub>3</sub> or COOH

Simple structure of 60, 240 and 960 rigid grafting sites from fullerene structure

Constant coverage density of 21 Å<sup>2</sup> per chain

•D. Dunphy, UNM/Sandia personal communication

Place each in decane, water and Brownian solvents.

# Effect of mixed-chain termination

Coating termination is an important secondary variable

Bundling:

- Mixed-chains decreased uniformity in the coating surface

- Mixed chains tended toward small tight bundles unless solvated

## Effect of solvent and backbone

Solvent quality is another important secondary variable

Homogeneous chains behaved largely as expected to solvent changes based on hydrophilic/phobic interactions

Mixed-chains decreased uniformity in the coating surface as chains tended toward small tight bundles unless solvated

## Surface initial conditions

---

- NPs placed at liquid/vapor interface of water
- All 12 particle type were began equilibrated in implicit solvent
- Simulation continued until vertical motion ceased

# Coated particles at a water surface

C10 with CH<sub>3</sub>

C10 with COOH

C18 with CH<sub>3</sub>

C18 with COOH

2 nm  
diameter

4 nm  
diameter

8 nm  
diameter

## Future direction: Surface interaction

---

- How will collections of particles behave at the surface?
- Can we preselect drivers of self-assembly by altering the particle coatings?

*COOH terminal group*

*CH<sub>3</sub> terminal group*

## Summary and conclusions

---

- Nanoscale forces between functionalized NPs can be found from fully-atomistic simulations
  - Contact forces between NPs are **velocity & separation dependent**
  - Coatings remove features of bare NPs – make more like macroscopic
  - The important regime for NP interactions in solution is  $F < 1\text{nN}$  making accurate force extraction difficult
  - Coarse-grained NPs will allow study of longer time and length scales
- Coating quality can be dramatically affected by geometry and secondarily by coating and solvent interactions
- “Poor” coatings could be exploited at surfaces and in the bulk to select structures during self-assembly
- **Resources now available to make significant inroads in understanding nanoparticle suspensions**
